but all with such horrifying oaths, that I made haste to get away from him.I told him exactly how everything had happened, and when I said I must go, and asked him to further me on my way, he made no sort of difficulty, but set about doing so at once.At nine o'clock, guided by Planchet, the little cavalcade set out, taking the route the carriage had taken.Here and there were new brick houses and shops, just set up by bustling, driving, and eager men of traffic from the Atlantic States; while, on the other hand, the old French mansions, with open casements, still retained the easy, indolent air of the original colonists; and now and then the scraping of a fiddle, a strain of an ancient French song, or the sound of billiard balls, showed that the happy Gallic turn for gayety and amusement still lingered about the place.Well, I know what I's gwyne to do: I's gwyne to set down here and listen tell I hears it agin."We bought merchandise, loaded a vessel with it, and set forth with a favorable wind.We set out from the kingdom of Dancali on the 15th of June, having taken our leave of the King, who after many excuses for everything that had happened, dismissed us with a present of a cow, and some provisions, desiring us to tell the Emperor of Aethiopia his father that we had met with kind treatment in his territories, a request which we did not at that time think it convenient to deny.I call to mind a winter landscape in Amsterdam - a flat foreground of waste land, with here and there stacks of timber, like the huts of a camp of some very miserable tribe; the long stretch of the Handelskade; cold, stone-faced quays, with the snow-sprinkled ground and the hard, frozen water of the canal, in which were set ships one behind another with their frosty mooring-ropes hanging slack and their decks idle and deserted, because, as the master stevedore (a gentle, pale person, with a few golden hairs on his chin and a reddened nose) informed me, their cargoes were frozen-in up-country on barges and schuyts.Thus the beauty of day, and that of summer, is set off by the horrors of night and winter. to put (something or someone) in a particular place.to set a vase on a table.Synonyms: plant, situate, locate, positionto place in a particular position or posture.Set the baby on his feet.to place in some relation to something or someone.We set a supervisor over the new workers.to put into some condition.to put or apply.to put in the proper position.to set a chair back on its feet.to put in the proper or desired order or condition for use.to distribute or arrange china, silver, etc., for use on (a table).to set the table for dinner.to place (the hair, especially when wet) on rollers, in clips, or the like, so that the hair will assume a particular style.to put (a price or value) upon something.He set $7500 as the right amount for the car.The teacher sets a high value on neatness.to fix the value of at a certain amount or rate; has beendefined, directly or indirectly, in terms of sets. Basic definitions and notation A set is a collection of objects, considered as a mathematicalobject in its own right. (A helpful metaphor for a set is a cardboardboxthe box can hold objects, and we can choose to think about theobjects in the box individually, or to think about the box and its contentscollectively as a single object.) The objects in a set are called theelements (or members) of the set; the elements are saidto belong to the set (or to be in the set), and the setis said to contain the elements. Usually the elements of a set areother mathematical objects, such as numbers, variables, or geometricpoints. Writing sets A set is often written by listing its elements between curlybraces{}. For example, a set containing the numbers 1,2,and3 would be written as {1,2,3}. When the elements of a set follow an obvious pattern but there are too manyof them to list explicitly, it is common to list the first few elements (toestablish the pattern) and the last element (to specify where the patternstops), with an ellipsis() in between to indicate that theelements in the middle were omitted. For instance, to write the set of positiveintegers from 1 to100, we can write{1,2,3,,100}. If no element is written afterthe ellipsis, the pattern is assumed to continue forever; so the set written{1,2,3,} contains all of the positive integers.Sometimes the elements of a set go on forever in bothdirectionsfor instance, the set of all integers (bothpositive and negative) can be written as{,3,2,1,0,1,2,3,}. A set can also be described in natural language using English phrases. Forexample, the set of all positive integers describes a particularset. It is important that the description be precise, so that there is no doubtabout whether a particular object is or is not an element of the set. A commonexample of an imprecise description is a phrase such as the numbersbetween 1 and10. This phrase has several ambiguities. Are thenumbers 1 and10 themselves elements of the set, or are they excluded? Areall real numbers between 1 and10 included, or only the integers?Finally, the phrase should probably be clearer about the fact that thesenumbers are to be considered as a set, rather than individually. A more precisedescription of this set might be the set of positive integers no greaterthan10 (if the numbers 1 and10 are in the set, and onlywhole numbers are included) or the set of real numbers between 1and10, exclusive (if the set includes numbers with fractionalparts, but not the numbers 1 and10 themselves). The symbol is used to mean is an element of, justas the symbol= is used to mean equals. For example, to saythat the number2 is an element of the set {1,2,3}, we canwrite 2{1,2,3}. To express the opposite,is not an element of, we put a slash through the symbol andwrite. For example, we can write4{1,2,3}. It is often useful to assign names to sets. These names are usually chosento be single letters, similar to the use of letters to represent numbers inalgebra. A very common convention is to use capital letters for the names ofsets and lower-case letters to represent the elements of sets. So, forinstance, if we assign the letterA to the set{1,2,3} by writing A={1,2,3}, wecan then say that 2A. We can also writeaA, by which we mean thatais a (possibly unknown) number that is an element of thesetAin other words, the value ofa mustbe either 1,2, or3. Equality of sets Two sets are said to be equal if every element of the first setis an element of the second set, and vice versa. For example, ifA={1,2,3} andB={2,3,1}, then the sets AandB are equal. Every element ofA is also anelement ofB, and every element ofB is also anelement ofA. We express set equality with an equals sign, soin this case we write A=B. When two sets areequal, they are considered to be the same set. It is important to remember thatequality between sets is a different concept than equality between numbers. One consequence of this definition of equality is that the order in whichthe elements of a set are listed is irrelevant. We care only about whichobjects are elements of the set, not the order they come in. So, for instance,the expressions {1,2,3} and {2,3,1} both describe thesame set. Another consequence is that the number of times an element is listed isirrelevant. The set {1,2,1,3,3,3} is equal to theset {1,2,3}, because every element of the first set is an elementof the second, and vice versa. (It does not matter that the numbers 1and3 are listed several times in the first set.) [Sometimes we need to use a collection of objects in which order isimportant. Such a collection is called a sequence or anordered list. An example is the use of ordered pairs ofthe form (x,y) to represent points in atwo-dimensional plane; the point(2,5) is different from thepoint(5,2). Similarly, we sometimes need a collection of objects inwhich it is meaningful for an element to appear more than once. Such acollection is called amultiset. Whenwe refer to a set, however, it is to be understood that the order andrepetition of the elements is irrelevant.] Sets containing other sets The elements of a set can be anythingeven other sets. For example,suppose we have two sets, A={1,2,3} andB={2,3,4,5}. Think of A asa box containing the numbers 1,2, and3, and Bas abox containing the numbers 2,3, 4, and5. There is nothing stoppingus from putting the boxA and the boxBtogether inside a larger boxC. In the same way, we can make asetC containing the setA and thesetB as elements. We can write the setC as{A,B}, or, if we like, we can say C={{1,2,3},{2,3,4,5}}. A set containing other sets is like a box containing other boxes. In thiscase, the setC has two elements, which are the twosets A andB. These elements of thesetC are themselves sets; the setA has threeelements, and the setB has four elements. Therefore it is true that AC,because A is an element ofC. Similarly, it is truethat BC. Of course, it is also truethat, say, 1A, because the number1 is anelement of the setA. However, it is not true that 1C,because 1 is not an element of the setC. The only two elementsofC are the sets A andB, andneither of these two elements is the number1. (The setAcontains the number1, but Aitself is not thenumber1.) Returning to the box metaphor, we should think about elements of a set (abox) as the objects that are directly inside the box. Thenumber1 is not directly inside the boxC; instead, it ishidden inside the boxA. So 1is not an element of thesetC, but 1is an element of thesetA. Likewise, even though it is true that 2A andalso true that 2B, it is not true that2C, because the number2 is not directlyinside the boxC. Now lets consider the set D={1,2,3,2,3,4,5}, which is the same as the set {1,2,3,4,5} because theorder and repetition of the elements are irrelevant. The setDis different from the setCthese sets are notequal. To see this, it is enough to find a single element in one set that isnot an element of the other set. Well, the number1, for example, is anelement ofD but (as explained above) is not an elementofC; so the sets are not equal. Thinking of CandD as boxes, we see why they are not the same: thesetC is a box that contains two boxes (which themselves happento contain some numbers), whereas the setD is a box thatdirectly contains five numbers (and no boxes). As another example, consider the two sets E={1} andF={{1}}. These sets are not equal.The setE has one element, which is the number1; thesetF also has one element, but the single elementofF is another set, not a number. So, whereas thesetE is a box containing the number1, thesetF is a box containing a box containing the number1.(In other words, the setF is a boxcontainingEdo you see this?) Both of these aredifferent from the number1 itself. So it is true that1E, and in factEF (because the single elementofF is the setE), but it is not truethat 1F. Sets containing other sets are common in some areas of mathematics, but wewont see them very often in this course. (Mathematicians who work inthese areas often call a set containing other sets a collection ofsets or a family of sets to avoid the awkward phraseset of sets.) Cardinality The cardinality of a set is the number of elements that the setcontains. (Sometimes the cardinality of a set is simply called thesize of the set, because size is ashorter word; but cardinality is the technically correct term.) It is common to write|A| to mean the cardinality of thesetA. For example, ifA={1,4,8}, then|A|=3, because A has three elements. This isthe same notation as is used for the absolute value of a number, but contextmakes it clear what is meant: if the vertical bars surround a set, they referto the cardinality of the set. The cardinality of a set might be infinite. For instance, the cardinality ofthe set of positive integers, {1,2,3,}, isinfinite. The empty set We have been thinking of sets as boxes. What kind of set corresponds to theidea of an empty box? Clearly it must be a set that contains no elements atall. We call such a set an empty set. Since any two empty setscontain exactly the same elements (specifically, no elements at all), weconsider any two empty sets to be equal, and hence the same set. So we usuallyrefer to the empty set, because there is really only one. There are two common ways to write the empty set. The first way, as youmight expect, is{}. The other notation is a circle or a zero with aslash through it, which looks like. Both{}and are symbols for the empty set. Note that there is a difference between and{}. Thefirst is the empty set, which is an empty box. The second is a boxcontaining an empty box, so the second box is not emptyit has abox in it! Dont write{} when you mean the empty set,because {} refers to a set containing the empty set, which is not thesame as the empty set itself. The cardinality of the empty set is0, which makes sense, because theempty set contains no elements. The statementx is always false, no matter whatx is, because there is no such thing as an element of the emptyset. Above, we defined two sets A andB to be equal ifevery element ofA is an element ofB, and viceversa. If we remove the vice versa from this definition, we getthe definition of a subset. We say that a setA is a subset of asetB if every element ofA is also an elementofB. We use the symbol to mean is a subsetof; for example, AB meansAis a subset ofB. We can alsoturn this symbol the other way and write the sets in the other order to getBA; this means the same asAB. To write that Aisnot a subset ofB, we draw a slash through the subset symbol:AB. Intuitively, a subsetofB is a part ofB. For example, consider the sets C={1,2} andD={1,2,3,4}. The setCis a subset ofD, because every element ofC isalso an element ofD. So we can writeCD. A given set has many subsets; forexample, another subset ofD is {1,3,4}. To remember which direction to write the symbol, think about thecardinalities of the sets and the inequality symbol. If Ais a subset ofB, then B must contain at least asmany elements as Adoes (simply because B containsall of the elements ofA), so the cardinalityofB must be greater than or equal to the cardinalityofA. In other words, ABimplies that|A||B|. Note that the symbols above point in the same direction. There is a very important difference between the symbols and. The symbol is used to indicate an elementof a set, whereas the symbol is used to indicate a subset.For instance, consider the set D={1,2,3,4}. The set{2,4} is a subset ofD, because everyelement of{2,4} is also an element ofD, so it iscorrect to write {2,4}D. But theset{2,4} is not an element of the setD,because the four elements of the setD are all numbers(Ddoes not have any sets as elements), so it is incorrect towrite {2,4}D. On the other hand, thenumber2 is an element ofD, so it is correct to write2D; but the number2 is not a subsetofD (because the number2 is a number, not a set), so itis incorrect to write 2D. If we want to refer tothe subset ofD containing only the number2, we shouldwrite{2}, which is the set containing2 (note that the set{2}is different from the number2). The set{2} is a subsetofD, thatis, {2}D; but itis not an element ofD, because D does nothave any sets as elements, so it is incorrect to write{2}D. When A is a subset ofB, thesetB is occasionally called a supersetofA. We can also sayBcontainsA as a subset, butgreat care should be taken with the word contains, because, asnoted in the previous paragraph, there is a big difference between sayingBcontainsA as an element(meaning AB) and sayingBcontainsA as a subset (meaningAB). I will try to use the wordcontains only to refer to elements, not subsets. A careful reading of the definition of subset shows that every set is asubset of itself. For example, using the setD from above, itis obviously true that every element ofD is also anelement ofD, so by definition Dis asubset ofD. We often want to exclude this case, so we define aproper subset of a setB to be a subsetofB that is not Bitself. We writeAB to mean that Ais aproper subset ofB. [This usage of the symbols and to mean is a subset of (or equal to) and isa proper subset of, respectively, parallels the usage of the inequalitysymbols and< to mean is less than or equal to andis strictly less than, respectively.] The empty set is considered to be a subset of every set (including itself).This may seem like a rather odd convention. Perhaps the best justification forit comes from turning the definition of subset on its head and asking what itmeans for a setA notto be a subsetofB. From the definition, this must mean that there is someelement inA that is not an element ofB. Sowhat would it mean to say that the empty set is not a subsetofB? It would mean that there is some element in the empty setthat is not an element ofBbut this cannot be true,because there are no elements in the empty set! So, from this point ofview, it makes some amount of sense to say that the empty set is a subset ofevery set. [It should be noted that the usage of the symbols anddescribed above is not universal. Some authors use the symbol tomean is a subset of (for which we are using thesymbol) and introduce a new symbol, a subset symbolwith the equals bar crossed out, to mean is a propersubset of (for which we are using the symbol).] Sets of numbers There are some sets of numbers that are so commonly useful that they havespecial symbols. Double-struck capital letters, sometimes called blackboard boldletters, are often used (in particular, the letters ,,, and). Alternatively, the letters may simply be typeset inboldface. [Due to the possibility that unusual symbols, such as blackboardbold, may not appear correctly in all Web browsers, I will use simple boldfaceletters here.] The set of all real numbers, both positive and negative (and zero), iscalledR (for real). The set of real numbers includesall numbers commonly encountered in an algebra, trigonometry, or calculuscourse. (It does not contain complex numbers suchas1.) The set of integers (positive, negative, and zero) is calledZ(from the German word Zahlen, meaningnumbers). In other words,Z={,3,2,1,0,1,2,3,}. The set of natural numbers is calledN (fornatural). The set of natural numbers contains all positiveintegers and no negative integers. Unfortunately, there is no consensus onwhether zero should be considered a natural number. Some authors include0in the setN, while others do not. The reason for this lack ofconsistency is that sometimes it is useful to include zero and sometimes not,depending on the situation. So mathematicians use whichever definition suitsthem best at the timebut they are aware of the differences in usage, sothey are always very careful to state exactly which definition they are usingin any particular case to avoid any confusion or ambiguity, and once they havedecided on a definition they stick with it. For this class, lets agreethat 0is not a natural number unless specified otherwise. Inother words, unless otherwise stated, we will use the symbolN torepresent the set {1,2,3,}. If we wish to refer tothe set {0,1,2,3,} when we are using thisdefinition ofN, we can always write N{0}(well talk about the meaning of the symbol in a bit).Alternatively, the terms positive integer and non-negativeinteger are always unambiguous: zero is not positive, but it isnon-negative. Therefore, another way to refer to the set{1,2,3,} is the set of positiveintegers, while {0,1,2,3,} is theset of non-negative integers. Finally, the set of rational numbers is calledQ (from the wordquotient). A rational number is a number that can bewritten exactly as a fraction, or quotient, of two integers. For example, thenumber2/3 is a rational number, as is the number7/2. Allintegers are rational numbers, because any integer can be written as a fractionwith denominator1; for instance, the integer5 can be writtenas5/1. Other examples of rational numbers include numbers that can bewritten as a terminating decimal (for example, the number8.13 can bewritten as 813/100) or as a repeating decimal (for example, thenumber0.333 can be written as1/3). Not all real numbersare rational, however. Examples of real numbers that cannot be written exactlyas a fraction of two integers include2and; the decimal expansions of these numbers go on foreverand never repeat. In this course we will not have much of a need to distinguishrational numbers from real numbers, so we will rarely (if ever) use thesymbolQ. Note that these four sets of numbers are (proper) subsets of each other:NZQR. Set-builder notation Listing all of the elements of a set is fine as long as the set is not toobig. For larger sets, we can skip some of the elements by writing anellipsis(), as we have seen, but this is only feasible when theelements follow a pattern that can be clearly seen in the first few elements.This is not always the case. For example, the set of all prime numbers between100 and500 could be written as{101,103,107,,499}, but this is not a veryhelpful thing to write because it is very difficult to guess the correctpattern from these numbers alone (and this expression does not rule outincorrect patterns such as the set of all odd numbers between 100and500, except multiples of5). In situations like this, it is often better to describe a set by specifyinga condition for membership. (Our English description of the set abovedoes exactly this; it says, in effect, that the condition for a number to anelement of the set is that the number must be prime and between 100and500.) When we want to describe a set in this way, we can useset-builder notation. When we use set-builder notation, we must first establish the universalset (sometimes called the domain of discourse or theuniverse of discourse), which is the set of all possible objectsunder consideration. For example, we might say that the universal setisR, the set of all real numbers; or perhapsZ, theset of integers. Another possibility is to use a previously defined set as theuniversal set. If we have defined A={1,2,3},for instance, we can use A as the universal set. Once we have chosen a universal set, we may build a set bychoosing all of the elements of the universal set that satisfy a specifiedcondition. For example, if the universal set isR, we can define asetB to be, say, the set of all elements ofR thatare greater than17. (So B contains the numbers 18and29.4, for example, but does not contain 11.26 or30.) ThissetB can be written using set-builder notation as B={xR|x>17}. In set-builder notation, the vertical bar| should be read assuch that or satisfying the condition that. So theexpression above can be read as Bis the set thatcontains every elementx in the universal setRsatisfying the condition that x>17. Note that the universal set is specified on the left side of the verticalbar, and a name is given to represent an arbitrary element of the universal setby using the symbol. On the right side of the bar is the conditionthat the element must satisfy in order to be a member of the set we arebuilding. The name for the arbitrary element (xin the exampleabove) can be anything; the example above means exactly the same as, say, B={zR|z>17}, or even B={R|>17}, though is not a very common variable name (and it is likely to causesome amount of puzzlement, so it should probably be avoided). Why is the universal set important? The answer is that a set described usingset-builder notation will always be a subset of the universal set. Consider theset C={xN|x>17}, which is defined in exactly the same way as the setB aboveexcept that the universal set has been changed toN. The setsB andC have many elements in common; for example,the number20 is an element of both B andC.However, since C has been built out of elements ofNrather than elements ofR, the setC contains only(positive) integers and does not contain any number with a fractional part. So,for instance, the number23.456 is an element ofB but isnot an element ofC. As another example of set-builder notation, consider the set D={nN|n10}. What does this mean? Reading from left to right, one symbol at a time, weread, Dis the set that contains everyelementn in the universal setN satisfying thecondition that n10. Here, the universal setis the setN of natural numbers (which we have agreed does notinclude0), so we see that D={1,2,3,4,5,6,7,8,9,10}. Note that a set described using set-builder notation might be empty, if noelements in the universal set satisfy the specified condition! For example, theset E={nN|n
