(polysaccharide). Glucose is a monosaccharide derived from sugars (fructose, sucrose, galactose, etc.). Glucose is the body's main preferred source of fuel for cellular respiration. As glucose is absorbed into the bloodstream as a result of digestion, it can be used immediately for cellular respiration or stored as glycogen in the liver and skeletal muscles for use later. Glucose is the only nutrient (as opposed to fats or proteins) utilized as a source of energy by the tissues in the brain. In plants, glucose can be used to form various storage or structural polysaccharides. Excess sugars in plants are stored as starch in roots and other tissues. Cellulose is the most abundant structural polysaccharide in plants and a major component of the cell wall for protecting and supporting the whole organism. Although cellulose is in great abundance, it is generally an inaccessible source of carbohydrates to most animals.

Lipids are a class of organic macromolecules composed primarily of carbon and hydrogen atoms; they include fats, phospholipids, waxes and steroids. Fats are stored in the body in the form of triglycerides (body fat) and provide a second source of energy utilized by the body for metabolic processes. Lipids also serve an important role as structural components in cell membranes, synthesis of lipoproteins, hormones, cushioning body organs against injury and insulating the body.

Proteins are polymers of amino acids and form the third group of organic macromolecules. Proteins are the least preferred source of energy by the body. This is because proteins are "expensive" to construct and better used for other metabolic processes. However, proteins are a vital component of an organism's anatomy and physiology. They are essential for biochemical reactions, necessary for metabolic processes to take place and are integral to the structure of
